**Eukaryotic cell division genes and their use in diagnosis and treatment of
proliferative diseases**

5

In a first aspect, the present invention is related to the significant functional role of several *C. elegans* genes and of their corresponding gene products in cell division and proliferation processes that could be identified by means of RNA-mediated interference (RNAi).

10 In a second aspect, the invention relates to the identification and isolation of functional orthologues of said genes and their gene products found in other eukaryotic species, in particular man, including all biologically-active derivatives thereof.

In a third aspect, the present invention includes the use of said genes and gene products (including said orthologues) in the development or isolation of anti-proliferative agents for instance their use in appropriate screening assays and in methods for diagnosis and
15 treatment of proliferative diseases.

In a forth aspect, the invention relates to antibodies to said gene products and their use in the development or isolation of anti-proliferative agents and in methods for diagnosis and treatment of proliferative diseases.

20 In a fifth aspect, the present invention is related to the use of these genes and gene products for developing structural models or other models for evaluating drug binding and efficacy as well as to any other uses which are derived from the new functions described here and which will become apparent from the disclosure of the present application for any person skilled in the art.

25 Metazoan cell division consists of an extremely complex, highly regulated set of cellular processes which must be tightly co-ordinated, perfectly timed, and closely monitored in order to ensure the correct delivery of cellular materials to daughter cells. Defects in these processes are known to cause a wide range of so-called proliferative diseases, including all forms of cancer. Since cell division represents one of the few, if not the only cellular
30 process that is common to the aetiology of all forms of cancer, its specific inhibition has

- 2 -

long been recognised as a preferred site of therapeutic intervention. Although mitotic inhibitor drugs are recognised as one of the most promising classes of chemotherapeutic agent, screening attempts to find new drug candidates in this class have been undermined by the strong inherent tendency of such screens to identify agents that target a single protein, tubulin. Tubulin polymerises to form microtubules, the primary cytoskeletal elements needed for mitotic spindle function and chromosome segregation. Microtubule functions, however, are ubiquitously needed in almost all cell types, whether dividing or not, a fact which therefore explains many of the unwanted side effects caused by anti-tubulin drugs.

Perhaps the best known example of a highly successful anti-neoplastic drug that targets tubulin is provided by paclitaxel, and its marketed derivative, Taxol, from Bristol Meyers Squibb. Its applicability has indeed been seriously limited by difficulties in determining an adequate dosing regimen due to a range of problematic side effects. Taxol treatment has resulted in anaphylaxis and severe hypersensitivity reactions characterised by dyspnea and hypotension requiring treatment, angioedema, and generalised urticaria in 2-4% of patients in clinical trials. All Taxol is administered after pretreatment with corticosteroids and despite pretreatment, fatal reactions have occurred. Severe conductance abnormalities resulting in life-threatening cardiac arrhythmia occur in less than 1 percent of patients and must be treated by insertion of a pacemaker. Taxol can cause fetal harm or fetal death in pregnant women. Furthermore, administration is commonly accompanied by tachycardia, hypotension, flushing, skin reactions and shortness-of-breath (mild dyspnea).

Despite these shortcomings, Taxol has been hailed by many as the most successful new anti-cancer therapeutic of the last three decades. Clearly, there is good justification for attempting to add to the list of mitotic inhibitors used to treat cancer. However, additional drugs that target tubulin or interfere with microtubule dynamics may be expected to have similar applicability and limitations as Taxol.

- 3 -

The task of the present invention therefore is to find new potential target proteins/genes for therapeutical drugs other than tubulin that are essential for completion of mitosis. These proteins/genes may provide novel targets to screen for new anti-neoplastic or cytotoxic anti-cancer agents.

5

Unfortunately, until now, the systematic identification of such target proteins/genes using genetic screening methods has been difficult in metazoans, and has relied heavily on the use of the unicellular yeast. Several major advances in the use of certain metazoan model organisms, particularly the nematode worm *Caenorhabditis elegans*, have now begun to offer new ways of bridging this gap.

10

The above-mentioned task of the invention to find new potential target proteins/genes for therapeutical drugs other than tubulin involved in mitosis processes is solved by a screening assay in *C. elegans* based on 'genomic RNA mediated interference (RNAi)' combined with a highly probative microscopic assay for documenting the first rounds of embryonic cell division (Sulston *et al.*, The embryonic cell lineage of the nematode *Caenorhabditis elegans*. *Dev. Biol.* 100, 64-119 (1983); Gönczy *et al.*, Dissection of cell division processes in the one cell stage *Caenorhabditis elegans* embryo by mutational analysis. *J Cell Biol* 144, 927-946 (1999)). With this combination of techniques a selected gene and also a variety of selected genes can be functionally characterized with unprecedented speed and efficiency.

15

20

The nematode *C. elegans* exhibits an almost entirely translucent body throughout its development, thereby offering unparalleled microscopic access for exquisitely detailed cytological documentation, even for the earliest steps of embryogenesis. This important feature, along with its short life cycle (3-5 days), its ease of cultivation, and its low maintenance costs, has helped make *C. elegans* arguably the best studied of all metazoans. Also, sequence data are now available for over 97% of the *C. elegans* genome (*C. elegans* Sequencing Consortium. Genome sequence of the nematode *C. elegans*: a platform for investigating biology. *Science* 282, 2012-2018 (1998)). Thus, *C. elegans* has proven to be

25

30

- 4 -

an ideal organism for applying the new technique of RNA-mediated interference (RNAi). This technique consists in the targeted, sequence-specific inhibition of gene expression, as mediated by the introduction into an adult worm of double-stranded RNA (dsRNA) molecules corresponding to portions of the coding sequences of interest (Fire *et al.*, Potent and specific genetic interference by double-stranded RNA in *Caenorhabditis elegans*. *Nature* 391, 806-811 (1998)). For the vast majority of *C. elegans* genes tested to date, this has been shown to yield a sequence-specific inhibition of the targeted gene's expression, accompanied by clearly detectable loss of function phenotypes in the treated worm's F1 progeny (and even in some cases, in the treated worm itself).

10

A large-scale RNAi technique-based screen was performed for 2,232 (that means 96%) of the predicted open reading frames on chromosome III of *C. elegans* which is described in detail in Gönczy *et al.*, "Functional genomic analysis of cell division in *C. elegans* using RNAi of genes on chromosome III" *Nature* 408, 331-336 (2000). For the performance of this large-scale screen double-stranded RNA corresponding to the individual open reading frames was produced and micro-injected into adult *C. elegans* hermaphrodites, and the resulting embryos were analysed 24 hours later using time-lapse DIC microscopy.

15

Besides others, the *C. elegans* genes H38K22.2 (Genbank/EMBL ID: AL024499, provided in SEQ ID NO. 1 - 3), C02F5.1 (Genbank/EMBL ID: L14745; , provided in SEQ ID NO. 4 and 5) and F10E9.8 (GenBank/EMBL ID: L10986; provided in SEQ ID NO. 6 and 7) gave rise to a phenotype detectable by the DIC-assay implying a functional role of these genes in metazoan cell division processes.

20

In at least one case (for H38K22.2) it had also been possible to identify a structurally and functionally homologous gene, a so-called orthologous gene, in another species, in particular *Homo sapiens*, namely the human orthologue RP42.

25

For the mouse orthologue of the RP42 gene it had merely been known that the gene shows a strongly developmentally regulated expression, particularly in proliferating neuroblasts from which neocortical neurons originate (Mas *et al.*, "Cloning and expression of a novel gene, RP42, mapping to an autism susceptibility locus on 6Q16" *Genomics* 1; 65 (1), 70-74 (2000)). The functional role of RP42 in cell division and proliferation processes that

30

- 5 -

makes it an excellent tool for the development or identification of drugs for diagnosis and/or therapy of proliferative diseases was not known so far.

With the essential function of said genes in cell division and proliferation known, these newly identified target genes and their corresponding gene products, any homologues, orthologues and derivatives thereof represent excellent tools for use in the development and isolation of a wide range of therapeutics including anti-proliferative agents and in the development of methods for diagnosis and treatment of proliferative diseases.

Therefore, in a first aspect, the present invention relates to isolated nucleic acid molecules encoding a polypeptide functionally involved in cell division and proliferation or a fragment thereof and comprising a nucleic acid sequence selected from the group consisting of:

(a) the nucleic acid sequences presented in SEQ ID NO. 1 to 3, SEQ ID NO. 4 to 5, SEQ ID NO. 6 to 7, SEQ ID NO. 12 and fragments thereof and their complementary strands,

(b) nucleic acid sequences encoding polypeptides that exhibit a sequence identity with SEQ ID NO. 8, SEQ ID NO. 9, SEQ ID NO. 10, SEQ ID NO. 11 or SEQ ID NO. 13 of at least 25 % over 100 residues and/or which are detectable in a computer aided search using the blast sequence analysis programs with an e-value of at most 10^{-30} ,

(c) nucleic acid sequences which are capable of hybridizing with the nucleic acid sequences of (a) or (b) under conditions of medium stringency,

(d) nucleic acid sequences which are degenerate as a result of the genetic code to any of the sequences defined in (a), (b) or (c).

- 6 -

The above mentioned fragments of the isolated nucleic acid molecules may comprise a at least 15 nucleotides and preferably at least 20 nucleotides.

Additionally the above mentioned isolated nucleic acid molecules may be single or double-stranded DNA-molecules as well as single- or double-stranded RNA-molecules.

5

a):

The nucleic acid sequences of those nucleic acid molecules encoding a polypeptide functionally involved in cell division and proliferation as mentioned in a) are provided in the sequence listing

- 10 as SEQ ID NO. 1 - 3 (*C. elegans* genes H38K22.2 (Genbank/EMBL ID: AL024499)),
as SEQ ID NO. 4 and 5 (*C. elegans* gene C02F5.1 (Genbank/EMBL ID: L14745)),
as SEQ ID NO. 6 and 7 (*C. elegans* gene F10E9.8 (GenBank/EMBL ID: L10986)) and
as SEQ ID NO. 12 (the human H38K22.2 orthologue, the RP42 protein (NCBI Accession No. AF292100)).

- 15 The corresponding deduced amino acid sequences of these target genes are disclosed in SEQ ID NO. 8 (for H38K22.2a), in SEQ ID NO. 9 (for H38K22.2b), in SEQ ID NO. 10 (for C02F5.1), in SEQ ID NO. 11 (for F10E9.8) and in SEQ ID NO. 13 (for RP42).

b):

- 20 Additionally, the present invention also comprises isolated nucleic acid molecules that are structurally and functionally homologous counterparts (particularly orthologues) of at least one of said target genes as disclosed in SEQ ID NO 1 to 7 or 12.

- Those homologous nucleic acid molecules may encode polypeptides that exhibit a sequence identity with SEQ ID NO. 8, SEQ ID NO. 9, SEQ ID NO. 10, SEQ ID NO. 11 or
25 SEQ ID NO. 13 of at least 25 % over 100 residues, preferably of at least 30 % over 100 residues, more preferably of at least 35 % over 100 residues and most preferably at least 40 % over 100 residues.

- 7 -

Fig. 5 shows that the aforementioned sequence identities are significant homologies that are appropriate to identify a polypeptide as an orthologue of the target proteins as depicted in SEQ ID NO. 8 -11, and 13. Fig. 5 shows a multiple sequence alignment of the H38K22.2a family on protein level generated with a BLAST sequence analysis program. In this alignment the two *C. elegans* splice variants H38K22.2a and H38K22.2b are compared to their corresponding orthologues in *Drosophila* (CG7427), in mouse (AAF04863) and in *Homo sapiens* (AAH09478). The statistics in Fig 5 for the alignments show that the sequence identity on protein level between the *C. elegans* clone H38K22.2a and its human orthologue (AAH09478) is 36 % over 299 residues. Similarly, the sequence identities between *C. elegans* clone H38K22.2b (the other splice variant) and its human orthologue is 36 % over 238 residues. It is obvious to anyone skilled in the art that these sequence homologies are significant homologies and that therefore the human clone with the accession No. AAH09478 is unambiguously identified as the human orthologue of the *C. elegans* clones H38K22.2a and H38K22.2b.

The invention also comprises isolated nucleic acid molecules that are detectable in a computer aided search using one of the BLAST sequence analysis programs with an e-value of at most 10^{-30} , preferably with an e-value of at most 10^{-35} , more preferably with an e-value of at most 10^{-40} .

Fig. 5 shows that the aforementioned e-values characterize significant sequence homologies that are appropriate to identify a polypeptide as an orthologue of the target proteins as depicted in SEQ ID NO. 8 -11, and 13.

The BLAST sequence analysis programs are programs used for sequence analysis that are publically available and known to anyone skilled in the art. When sequence alignments are done by a BLAST sequence analysis program, most of those programs calculate so called "e-values" to characterize the grade of homology between the compared sequences. Generally a small e-value characterizes a high sequence identity / homology, whereas larger e-values characterize lower sequence identities / homologies.

"Homology" means the degree of identity between two known sequences. As stated above, homologies, that means sequence identities, may suitably be determined by means of computer programs known in the art. The degree of homology required for the sequence variant will depend upon the intended use of the sequence. It is well within the capability

- 8 -

of a person skilled in the art to effect mutational, insertional and deletional mutations which are designed to improve the function of the sequence or otherwise provide a methodological advantage.

5 c):

The present invention further relates to isolated nucleic acid sequences or fragments thereof which are capable of hybridizing with the nucleic acid sequences of (a) or (b) under conditions of medium/high stringency.

10 The grade of sequence identity between a first and a second nucleic acid molecule can also be characterized by the capability of the first nucleic acid molecule to hybridize under certain conditions to a second nucleic acid molecule.

Suitable experimental conditions for determining whether a given DNA or RNA sequence "hybridizes" to a specified polynucleotide or oligonucleotide probe involve presoaking of the filter containing the DNA or RNA to examine for hybridization in 5 x SSC (sodium chloride/sodium citrate) buffer for 10 minutes, and prehybridization of the filter in a
15 solution of 5 x SSC, 5 x Denhardt's solution, 0,5 % SDS and 100 mg/ml of denaturated sonicated salmon sperm DNA (Maniatis et al., 1989), followed by hybridization in the same solution containing a concentration of 10 ng/ml of a random primed (Feinberg, A.P. and Vogelstein, B. (1983), *Anal. Biochem.* 132:6-13), ³²P-dCTP-labeled (specific activity > 1 x
20 10⁹ cpm/μg) probe for 12 hours at approximately 45°C. The filter is then washed twice for 30 minutes in 2 x SSC, 0,5% SDS at at least 55°C (low stringency), at least 60°C (medium stringency), preferably at least 65°C (medium/high stringency), more preferably at least 70°C (high stringency) or most preferably at least 75°C (very high stringency). Molecules to which the probe hybridizes under the chosen conditions are detected using an x-ray film.

25

d):

The present invention further relates to isolated nucleic acid molecules or fragments thereof which are degenerate as a result of the genetic code to any of the sequences defined in (a), (b) or (c).

- 9 -

The application of automated gene synthesis provides an opportunity for generating sequence variants of the naturally occurring genes. It will be appreciated, for example, that polynucleotides coding for the same gene products can be generated by substituting synonymous codons for those represented in the naturally occurring polynucleotide sequences as identified herein. Such sequences will be referred to as "degenerate" to the naturally occurring sequences. In addition, polynucleotides coding for synthetic variants of the corresponding amino acid sequences can be generated which, for example, will result in one or more amino acids substitutions, deletions or additions. Also, nucleic acid molecules comprising one or more synthetic nucleotide derivatives (including morpholinos) which provide said nucleotide sequence with a desired feature, e.g. a reactive or detectable group, can be prepared. Synthetic derivatives with desirable properties may also be included in the corresponding polypeptides. All such derivatives and fragments of the above identified genes and gene products showing at least part of the biological activity of the naturally occurring sequences or which are still suitable to be used, for example, as probes for, e.g. identification of homologous genes or gene products, are included within the scope of the present invention.

Having herein provided the nucleotide sequences of various genes functionally involved in cell division and proliferation, it will be appreciated that automated techniques of gene synthesis and/or amplification may be used to isolate said nucleic acid molecules *in vitro*. Because of the length of some coding sequences, application of automated synthesis may require staged gene construction, in which regions of the gene up to about 300 nucleotides in length are synthesized individually and then ligated in correct succession for final assembly. Individually synthesized gene regions can be amplified prior to assembly, using polymerase chain reaction (PCR) technology. The technique of PCR amplification may also be used to directly generate all or part of the final genes/nucleic acid molecules. In this case, primers are synthesized which will be able to prime the PCR amplification of the final product, either in one piece or in several pieces that may be ligated together. For this purpose, either cDNA or genomic DNA may be used as the template for the PCR amplification. The cDNA template may be derived from commercially available or self-constructed cDNA libraries.

- 10 -

In a second aspect, the invention relates to nucleic acid probes comprising a nucleic acid sequence as previously characterized under (a) to (d) which may be a polynucleotide or an oligonucleotide comprising at least 15 nucleotides containing a detectable label.

These nucleic acid probes may be synthesized by use of DNA synthesizers according to standard procedures or, preferably for long sequences, by use of PCR technology with a selected template sequence and selected primers. In the use of the nucleotide sequences as probes, the particular probe may be labeled with any suitable label known to those skilled in the art, including radioactive and non-radioactive labels. Typical radioactive labels include ^{32}P , ^{125}I , ^{35}S , or the like. A probe labeled with a radioactive isotope can be constructed from a DNA template by a conventional nick translation reaction using a DNase and DNA polymerase. Non-radioactive labels include, for example, ligands such as biotin or thyroxine, or various luminescent or fluorescent compounds. The probe may also be labeled at both ends with different types of labels, for example with an isotopic label at one end and a biotin label at the other end. The labeled probe and sample can then be combined in a hybridization buffer solution and held at an appropriate temperature until annealing occurs.

The invention also includes an assay kit comprising either an isolated nucleic acid molecule as defined above or a fragment thereof or a probe as defined above in a suitable container.

Duplex formation and stability depend on substantial complementarity between the two strands of a hybrid and a certain degree of mismatch can be tolerated. Therefore, the nucleic acid molecules and probes of the present invention may include mutations (both single and multiple), deletions, insertions of the above identified sequences, and combinations thereof, as long as said sequence variants still have substantial sequence homology to the original sequence which permits the formation of stable hybrids with the target nucleotide sequence of interest.

The above identified nucleic acid molecules and probes coding for polypeptides functionally involved in cell division and proliferation or a part thereof will have a wide range of useful applications, including their use for identifying homologous, in particular orthologous, genes in the same or different species, their use in screening assays for

- 11 -

identification of interacting drugs that inhibit, stimulate or effect cell division or proliferation, their use for developing computational models, structural models or other models for evaluating drug binding and efficacy, and their diagnostic or therapeutic use for detection or treatment of diseases associated with anomalous and/or excessive cell division
5 or proliferation, in particular neoplastic diseases, including both solid tumors and hemopoietic cancers, or coronary restenosis. Exemplary neoplastic diseases include carcinomas, such as adenocarcinomas and melanomas; mesodermal tumors, such as neuroblastomas and retinoblastomas; sarcomas and various leukemias; and lymphomas. Of particular interest are tumors of the breast, ovaries, gastrointestinal tract, liver, lung,
10 thyroid glands, prostate gland, brain, pancreas, urinary tract, and salivary glands. Still more specific, tumors of the breast, ovaries, lung, colon, and lymphomas are contemplated.

In a third aspect, the present invention relates to the use of the above identified nucleic acid
15 molecules and probes for diagnostic purposes. This diagnostic use of the above identified nucleic acid molecules and probes may include, but is not limited to the quantitative detection of the expression of said target genes in biological probes (preferably, but not limited to cell extracts, body fluids, etc.), particularly by quantitative hybridization to the endogenous nucleic acid molecules comprising the above-characterized nucleic acid
20 sequences (particularly cDNA, RNA). An abnormal and/or excessive expression of said target genes involved in cell division may be diagnosed that way.

In a fourth aspect, the present invention relates to the use of the above identified nucleic acid molecules, probes or their corresponding polypeptides for therapeutical purposes.
25

This therapeutical use of the above identified nucleic acid molecules, probes or their corresponding polypeptides may include, but is not limited to the use of said nucleic acid molecules and their corresponding polypeptides for direct or indirect inhibition of the expression of said target genes and/or for inhibition of the function of said target genes.
30 Particularly gene therapy vectors, e.g. viruses, or naked or encapsulated DNA or RNA (e.g. an antisense nucleotide sequence) with the above-identified sequences might be suitable

- 12 -

for the introduction into the body of a subject suffering from a proliferative disease or from a disease affecting cell division for therapeutical purposes.

A particularly preferred therapeutical use of the above identified nucleic acid molecules or probes relates to their use in a therapeutical application of the RNAi technique, particularly in humans or in human cells.

Double-stranded RNA oligonucleotides effect silencing of the expression of gene(s) which are highly homologous to either of the RNA strands in the duplex. Recent discoveries reveal that this effect, called RNA interference (RNAi), that had been originally discovered in *C. elegans*, can also be observed in cells, particularly in human cells. Therefore the invention further comprises the use of double-stranded RNA oligonucleotides with the above identified nucleotide sequences (as stated in a) to d)), preferably with a length of at least 15 nucleotides (nt), more preferably with a length of at least 20 nt, for therapeutical silencing of the expression of genes involved in cell division or proliferation in cells of other species, particularly in human cells. This therapeutical use particularly applies to cells of an individual that suffers from a disease associated with anormalous and/or excessive cell division or proliferation, particularly a coronary restinosis or a neoplastic disease selected from the group consisting of lymphoma, lung cancer, colon cancer, ovarian cancer and breast cancer.

In a fifth aspect, the invention further comprises a nucleic acid construct or a recombinant vector having incorporated the nucleic acid molecules as defined in (a) to (d) or a fragment thereof.

“Nucleic acid construct“ is defined herein as any nucleic acid molecule, either single- or double-stranded, in which nucleic acid sequences are combined and juxtaposed in a manner which will not occur naturally. The vector may be any vector which can be conveniently subjected to recombinant DNA procedures. The choice of the vector will usually depend on the host cell into which it is to be introduced. The vector may be an extrachromosomal entity, the replication of which is independent of chromosomal replication, e.g. a plasmid. Alternatively, the vector may be one which, when introduced into a host cell, is integrated into the host cell genome and replicated together with the chromosome(s) into which it has been integrated.

- 13 -

The vector is preferably an expression vector in which the nucleic acid molecule as defined in (a) to (d) or a fragment thereof is operably linked to heterologous or homologous control sequences. The term "control sequences" is defined herein to include all components
5 which are necessary or advantageous for expression of the coding nucleic acid sequence. Such control sequences include, but are not limited to, a promoter, a ribosome binding site, translation initiation and termination signals and, optionally, a repressor gene or various activator genes. Control sequences are referred to as "homologous" if they are naturally linked to the coding nucleic acid sequence of interest and referred to as "heterologous" if
10 this is not the case. The term "operably linked" indicates that the sequences are arranged so that they function in concert for their intended purpose, i.e. expression of the desired protein.

The promoter may be any DNA sequence which shows transcriptional activity in the host
15 cell of choice and may be derived from genes encoding proteins either homologous or heterologous to the host cell.

Examples of suitable promoters for directing the transcription in a bacterial host are, e.g., the phage Lambda P_R or P_L promoters, the *lac*, *trp* or *tac* promoters of *E. coli*, the promoter
20 of the *Bacillus subtilis* alkaline protease gene or the *Bacillus licheniformis* alpha-amylase gene.

Examples of suitable promoters for directing the transcription in mammalian cells are, e.g., the SV40 promoter (Subramani et al., *Mol. Cell. Biol.* 1 (1981), 854-864), the MT-1
25 (metallothionein gene) promoter (Palmiter et al., *Science* 222 (1983), 809-814) or the adenovirus 2 major late promoter.

Examples of suitable promoters for use in insect cells are, e.g., the polyhedrin promoter (Vasuvedan et al., *Febs. Lett* 311, (1992), 7-11), the *Autographa californica* polyhedrosis
30 basic protein promoter (EP 397 485), or the baculovirus immediate early gene 1 promoter (US 5,155,037, US 5,162,222).

- 14 -

Examples of suitable promoters for use in yeast cells include promoters from yeast glycolytic genes (Hitzeman et al., *J. Biol. Chem.* 255 (1980), 1203-12080; Alber and Kawasaki, *J. Mol. Appl. Gen.* 1 (1982), 419-434) and the ADH2-4c promoter (Russell et al., *Nature* 304 (1983), 652-654).

5

The coding sequence may, if necessary, be operably linked to a suitable terminator, such as the human growth hormone terminator (Palmiter et al., *Science* 222, 809-814 (1983)), or a polyadenylation sequence. Also, to permit secretion of the expressed protein, a signal sequence may precede the coding sequence.

10

Further, the vector may comprise a DNA sequence enabling the vector to replicate in the host cell in question. Examples of such sequences are the origins of replication of the plasmids pUC19, pACYC177, pUB110, pE194, pAMB1 and pIJ702. Another example of such a sequence (when the host cell is a mammalian cell) is the SV40 origin of replication.

15

When the host cell is a yeast cell, suitable sequences enabling the vector to replicate are the yeast plasmid 2 μ replication genes REP 1-3 and origin of replication.

20

The vector may also comprise a selectable marker, e.g. a gene coding for a product which complements a defect in the host cell, such as the gene coding for dihydrofolate reductase (DHFR) or a gene which confers resistance to a drug, e.g. ampicillin, kanamycin, tetracyclin, chloramphenicol, neomycin or hygromycin.

25

A number of vectors suitable for expression in prokaryotic or eukaryotic cells are known in the art and several of them are commercially available. Some commercially available mammalian expression vectors which may be suitable include, but are not limited to, pMC1neo (Stratagene), pXT1 (Stratagene), pSG5 (Stratagene), pcDNAI (Invitrogen), EBO-pSV2-neo (ATCC 37593), pBPV-1(8-2) (ATCC 37110), pSV2-dhfr (ATCC 37146).

30

In a sixth aspect, the invention comprises host cells into which the nucleic acid construct or the recombinant vector is introduced. These host cells may be prokaryotic or eukaryotic, including, but not limited to, bacteria, fungal cells, including yeast and filamentous fungi,

- 15 -

mammalian cells, including, but not limited to, cell lines of human, bovine, porcine, monkey and rodent origin, and insect cells including, but not limited to, drosophila derived cell lines.

- 5 The selection of an appropriate host cell will be dependent on a number of factors recognized by the art. These include, e.g., compatibility with the chosen vector, toxicity of the (co)products, ease of recovery of the desired protein or polypeptide, expression characteristics, biosafety and costs.

Examples of suitable prokaryotic cells are gram positive bacteria such as *Bacillus subtilis*,
10 *Bacillus licheniformis*, *Bacillus brevis*, *Streptomyces lividans* etc. or gram negative bacteria such as *E. coli*.

The yeast host cell may be selected from a species of *Saccharomyces* or *Schizosaccharomyces*, e.g. *Saccharomyces cerevisiae*. Useful filamentous fungi may be selected from a species of *Aspergillus*, e.g. *Aspergillus oryzae* or *Aspergillus niger*.

- 15 Cell lines derived from mammalian species which may be suitable and which are commercially available include, but are not limited to, COS-1 (ATCC CRL 1650) COS-7 (ATCC CRL 1651), CHO-K1 (ATCC CCL 61), 3T3 (ATCCL 92), NIH/3T3 (ATCC CRL 1658), HeLa (ATCCL 2), and MRC-5 (ATCC CCL 171).

- 20 The recombinant vector may be introduced into the host cells according to any one of a number of techniques including, but not limited to, transformation, transfection, protoplast fusion, and electroporation.

- The recombinant host cells are then cultivated in a suitable nutrient medium under
25 conditions permitting the expression of the protein of interest. The medium used to cultivate the cells may be any conventional medium suitable for growing the host cells, such as minimal or complex media containing appropriate supplements. Suitable media are available from commercial suppliers or may be prepared according to published recipes (e.g. in catalogues of the American Type Culture Collection).

- 16 -

Identification of the heterologous polypeptide expressing host cell clones may be done by several means, including, but not limited to, immunological reactivity with specific antibodies.

5 In a seventh aspect, the invention is related to a method for producing a polypeptide functionally involved in cell division and proliferation or a fragment thereof in a host cell comprising the steps

(i) transferring the expression vector with an operably linked nucleic acid molecule as defined in (a) to (d) into a suitable host cell, and

10 (ii) cultivating the host cells of step (i) under conditions which will permit the expression of said polypeptide or fragment thereof and

(iii) optionally, secretion of the expressed polypeptide into the culture medium.

In an eighth aspect, the invention comprises a polypeptide functionally involved in cell division and proliferation or a fragment thereof comprising an amino acid sequence
15 selected from the group consisting of:

(a) the amino acid sequences depicted in SEQ ID NO. 8, 9, 10, 11 and 13 and fragments thereof,

(b) amino acid sequences which exhibit a sequence identity with the sequences of
20 (a) of at least 25 % over 100 residues, preferably of at least 30 % over 100 residues, more preferably of at least 35 % over 100 residues and most preferably of at least 40 % over a 100 residues and/or which are detectable in a computer aided search using the BLAST sequence analysis programs with an e-value of at most 10^{-30} , preferably with an e-value of at most 10^{-35} and most
25 preferably with an e-value of at most 10^{-40} ,

(c) amino acid sequences encoded by a nucleic acid molecule that is capable of hybridizing with the nucleic acid sequences of (a) or (b) or encoded by a nucleic acid molecule that is degenerate as a result of the genetic code to any of the sequences as defined in (a) or (b).

The heterologous polypeptide may also be a fusion polypeptide in which another polypeptide is fused at the N-terminus or the C-terminus of the polypeptide of interest or fragment thereof. A fused polypeptide is produced by fusing a nucleic acid sequence (or a portion thereof) encoding another polypeptide to a nucleic acid sequence (or a portion thereof) of the present invention. Techniques for producing fusion polypeptides are known in the art and include ligating the coding sequences so that they are in frame and the expression of the fusion polypeptide is under control of the same promotor(s) and terminator.

Expression of the polypeptides of interest may also be performed using *in vitro* produced synthetic mRNA. Synthetic mRNA can be efficiently translated in various cell-free systems, including but not limited to, wheat germ extracts and reticulocyte extracts, as well as efficiently translated in cell based systems including, but not limited to, microinjection into frog oocytes, preferably *Xenopus* oocytes.

In a ninth aspect, the invention involves antibodies against the above identified polypeptides and against immunogenic fragments thereof. The term "antibody" as used herein includes both polyclonal and monoclonal antibodies, as well as fragments thereof, such as Fv, Fab and F(ab)₂ fragments that are capable of binding antigen or hapten. The present invention also contemplates "humanized" hybrid antibodies wherein amino acid sequences of a non-human donor antibody exhibiting a desired antigen-specificity are combined with sequences of a human acceptor antibody. The donor sequences will usually include at least the antigen-binding amino acid residues of the donor but may comprise other structurally and/or functionally relevant amino acid residues of the donor antibody as well. Such hybrids can be prepared by several methods well known in the art (see e.g. WO 89/09622; WO 94/11509; Couto, *Hybridoma* 13 (1994), 215-219; Presta, *Cancer Research* 57 (1997), 4593-4599). The antibodies of the present invention will have a wide range of useful applications, including their use for affinity purification of the corresponding immunogenic (poly)peptides, their use for the preparation of anti-idiotypic antibodies, as well as their use as specific binding agents in various assays, e.g. diagnostic or drug-screening assays, or in a method for treatment of diseases associated with anomalous and/or excessive cell division or proliferation as exemplified above. Specifically, said

- 18 -

antibodies or suitable fragments thereof, particularly in humanized form, may be used as therapeutic agents in a method for treating cancer and other diseases associated with anomalous and/or excessive cell division or proliferation as exemplified above. Also, antibodies may be raised to the most characteristic parts of the above identified polypeptides and subsequently be used to identify structurally and/or functionally related polypeptides from other sources as well as mutations and derivatives of the above identified polypeptides.

To raise antibodies against the polypeptides of the present invention, there may be used as an immunogen either the intact polypeptide or an immunogenic fragment thereof, produced in a suitable host cell as described above or by standard peptide synthesis techniques.

Polyclonal antibodies are raised by immunizing animals, such as mice, rats, guinea pigs, rabbits, goats, sheep, horses etc., with an appropriate concentration of the polypeptide or peptide fragment of interest either with or without an immune adjuvant.

Acceptable immune adjuvants include, but are not limited to, Freund's complete adjuvant, Freund's incomplete adjuvant, alum-precipitate, water-in-oil-emulsion containing *Corynebacterium parvum* and tRNA.

In a typical immunization protocol each animal receives between about 0,1 µg and about 1000 µg of the immunogen at multiple sites either subcutaneously (SC), intraperitoneally (IP), intradermally or in any combination thereof in an initial immunization. The animals may or may not receive booster injections following the initial injection. Those animals receiving booster injections are generally given an equal amount of the immunogen in Freund's incomplete adjuvant by the same route at intervals of about three or four weeks until maximal titers are obtained. At about 7-14 days after each booster immunization or about weekly after a single immunization, the animals are bled, the serum collected, and aliquots are stored at about -20°C.

Monoclonal antibodies which are reactive with the polypeptide or peptide fragment of interest are prepared using basically the technique of Kohler and Milstein, Nature 256: 495-497 (1975). First, animals, e.g. Balb/c mice, are immunized using a protocol similar to that described above. Lymphocytes from antibody-positive animals, preferably

- 19 -

splenocytes, are obtained by removing spleens from immunized animals by standard procedures known in the art. Hybridoma cells are produced by mixing the splenocytes with an appropriate fusion partner, preferably myeloma cells, under conditions which will allow the formation of stable hybridomas. Fusion partners may include, but are not limited to:

5 mouse myelomas P3/NS1/Ag 4-1; MPC-11; S-194 and Sp 2/0. Fused hybridoma cells are selected by growth in a selection medium and are screened for antibody production. Positive hybridomas may be grown and injected into, e.g., pristane-primed Balb/c mice for ascites production. Ascites fluid is collected about 1-2 weeks after cell transfer and the monoclonal antibodies are purified by techniques known in the art. Alternatively, *in vitro*

10 production of monoclonal antibodies (mAb) is possible by cultivating the hybridomas in a suitable medium, e.g. DMEM with fetal calf serum, and recovering the mAb by techniques known in the art.

Recovered antibody can then be coupled covalently to a detectable label, such as a radiolabel, enzyme label, luminescent label, fluorescent label or the like, using linker

15 technology established for this purpose.

Antibody titers of ascites or hybridoma culture fluids are determined by various serological or immunological assays which include, but are not limited to, precipitation, passive agglutination, enzyme-linked immunosorbent antibody (ELISA) technique and radioimmunoassay techniques. Similar assays may be used to detect the presence of the

20 above identified polypeptides or fragments thereof in body fluids or tissue and cell extracts.

Assay kits for performing the various assays mentioned in the present application may comprise suitable isolated nucleic acid or amino acid sequences of the above identified genes or gene products, labelled or unlabelled, and/or specific ligands (e.g. antibodies)

25 thereto and auxiliary reagents as appropriate and known in the art. The assays may be liquid phase assays as well as solid phase assays (i.e. with one or more reagents immobilized on a support).

Unless otherwise specified, the manipulations of nucleic acids and polypeptides/-proteins can be performed using standard methods of molecular biology and immunology (see, e.g.

30 Maniatis et al. (1989), Molecular cloning: A laboratory manual, Cold Spring Harbor Lab., Cold Spring Harbor, NY; Ausubel, F.M. et al. (eds.) "Current protocols in Molecular

- 20 -

Biology". John Wiley and Sons, 1995; Tijssen, P., Practice and Theory of Enzyme Immunoassays, Elsevier Press, Amsterdam, Oxford, New York, 1985).

5 The invention further includes an assay kit comprising either the polypeptide as defined above or a fragment thereof or an antibody against said polypeptides as defined above or against immunogenic fragments thereof.

10 These recombinant polypeptides or fragments thereof as well as antibodies against those polypeptides or immunogenic fragments thereof will have a wide range of useful applications, including their use in screening assays for interacting drugs that inhibit, stimulate or effect the cell division or proliferation, their use for developing computational models, structural models or other models for evaluating drug binding and efficacy, and their use in a method for diagnosis or treatment of diseases associated with anomalous and/or excessive cell division or proliferation, in particular neoplastic diseases, including
15 both solid tumors and hemopoietic cancers, or coronary restenosis. Exemplary neoplastic diseases include carcinomas, such as adenocarcinomas and melanomas; mesodermal tumors, such as neuroblastomas and retinoblastomas; sarcomas and various leukemias; and lymphomas. Of particular interest are tumors of the breast, ovaries, gastrointestinal tract, liver, lung, thyroid glands, prostate gland, brain, pancreas, urinary tract, and salivary
20 glands. Still more specific, tumors of the breast, ovaries, lung, colon, and lymphomas are contemplated.

25 Therefore in a tenth aspect, the present invention explicitly includes the use of polypeptides as defined above or fragments thereof or of antibodies against said polypeptides or immunogenic fragments thereof in a screening assay for interacting drugs that inhibit, stimulate or effect the cell division or proliferation.

Such a screening assay for interacting drugs may particularly comprise, but is not limited to the following steps:

30

1. recombinant expression of said polypeptide or of an appropriate derivative thereof

- 21 -

2. isolation and optionally purification of the recombinantly expressed polypeptide or of its derivative, in particular by affinity chromatography
3. optionally labelling of the chemical compounds that are tested to interact with said polypeptide or its derivative and/or labelling of the recombinantly expressed polypeptide
4. immobilization of the recombinantly expressed polypeptide or of its derivative to a solid phase
5. binding of a potential interaction partner or a variety thereof to the immobilized polypeptide or its derivative
6. optionally one or more washing steps
7. detection and/or quantification of the interaction, in particular by monitoring the amount of label remaining associated with the solid phase over background levels.

Step 1 includes the recombinant expression of the above identified polypeptide or of its derivative from a suitable expression system, in particular from cell-free translation, bacterial expression, or baculovirus-based expression in insect cells.

Step 2 comprises the isolation and optionally the subsequent purification of said recombinantly expressed polypeptides with appropriate biochemical techniques that are familiar to a person skilled in the art.

Alternatively, these screening assays may also include the expression of derivatives of the above identified polypeptides which comprises the expression of said polypeptides as a fusion protein or as a modified protein, in particular as a GST-fusion protein or as a protein bearing a so called "tag"-sequence. These "tags"-sequences consist of short nucleotide sequences that are ligated 'in frame' either to the N- or to the C-terminal end of the coding region of said target gene. One of the most common tags that are used to label recombinantly expressed genes is the poly-Histidine-tag which encodes a homopolypeptide consisting merely of histidines. In this context the term "polypeptide" does not merely comprise polypeptides with the nucleic acid sequences of SEQ ID No. 1 bis 7, their naturally occurring homologues, preferably orthologues, more preferably human orthologues, in particular the RP42 gene (SEQ ID No. 12), but also derivatives of these polypeptides, in particular fusion proteins or polypeptides comprising a tag-sequence.

- 22 -

These polypeptides, particularly those labelled by an appropriate tag-sequence (for instance a His-tag) or by GST, may be purified by standard affinity chromatography protocols, in particular by using chromatography resins linked to anti-His-tag-antibodies or to anti-GST-antibodies which are both commercially available. Alternatively to the use of anti-tag- or anti-GST-antibodies or other 'label-specific' antibodies the purification may also involve the use of antibodies against said polypeptides. Screening assays that involve a purification step of the recombinantly expressed target genes as described above (step 2) are preferred embodiments of this aspect of the invention.

In a third - optional - step the compounds tested for interaction may be labelled by incorporation of radioactive isotopes or by reaction with luminescent or fluorescent compounds. Alternatively or additionally also the recombinantly expressed polypeptide may be labelled.

In a forth step the recombinantly expressed polypeptide is immobilized to a solid phase, particularly (but not limited) to a chromatography resin. The coupling to the solid phase is thereby preferably established by the generation of covalent bonds.

In a fifth step a candidate chemical compound that might be a potential interaction partner of the said recombinant polypeptide or a complex variety thereof (particularly a drug library) is brought into contact with the immobilized polypeptide.

In a sixth - optional - step one or several washing steps may be performed. As a result just compounds that strongly interact with the immobilized polypeptide remain bound to the solid (immobilized) phase.

In step 7 the interaction between the polypeptide and the specific compound is detected, in particular by monitoring the amount of label remaining associated with the solid phase over background levels.

Brief Description of the Drawings

Fig. 1 shows DIC microscopy images taken from time-lapse recording of the first two rounds of embryonic cell division in wild type *C. elegans*.

Fig. 2 shows DIC microscopy images taken from time-lapse recording of the first two rounds of embryonic cell division in *C. elegans* F1 progeny from F0 parent treated with ds RNA "300C3" or "340G12" directed against gene H38K22.2.

- 23 -

Fig. 3 shows DIC microscopy images taken from time-lapse recording of the first two rounds of embryonic cell division in *C. elegans* F1 progeny from F0 parent treated with dsRNA "307C1" directed against gene C02F5.1.

Fig. 4 shows shows DIC microscopy images taken from time-lapse recording of the first two rounds of embryonic cell division in *C. elegans* F1 progeny from F0 parent treated with ds RNA "305A12" directed against gene F10E9.8.

Fig 5 shows a multiple sequence alignment of the H38K22.2a family. Herein, the amino acid sequences of the two *C. elegans* splice variants H38K22.2a and H38K22.2b are compared to the amino acid sequences of their orthologues in *Drosophila* (CG7427), in mouse (AAF04863) and in homo sapiens (AAH09478).

The "statistics" refer to values that characterize the grade of homology between the individual sequences, as the e-value, the sequence identities and the conservatively changed residues (positives).

Description of the sequence protocol:

SEQ ID NO. 1 shows the unspliced DNA sequence common to both isoforms a and b of the *C. elegans* gene H38K22.2 (3104 bp).

SEQ ID NO. 2 shows the spliced DNA sequence of the *C. elegans* gene H38K22.2a isoform (1011 bp).

SEQ ID NO. 3 shows the spliced DNA sequence of the *C. elegans* gene H38K22.2b isoform (852 bp).

SEQ ID NO. 4 shows the unspliced DNA sequence of the *C. elegans* gene C02F5.1 (3308 bp).

SEQ ID NO. 5 shows the spliced DNA sequence of the *C. elegans* gene C02F5.1 (3033 bp).

SEQ ID NO. 6 shows the unspliced DNA sequence of the *C. elegans* gene F10E9.8

- 24 -

- (7097 bp).
- SEQ ID NO. 7 shows the spliced DNA sequence of the *C. elegans* gene F10E9.8 (3624 bp).
- 5 SEQ ID NO. 8 shows the deduced amino acid sequence of the *C. elegans* gene H38K22.2a isoform (336 aa).
- SEQ ID NO. 9 shows the deduced amino acid sequence of the *C. elegans* gene H38K22.2b isoform (283 aa).
- SEQ ID NO. 10 shows the deduced amino acid sequence of the *C. elegans* gene C02F5.1 (1010 aa).
- 10 SEQ ID NO. 11 shows the deduced amino acid sequence of the *C. elegans* gene F10E9.8 (1207 aa).
- SEQ ID NO. 12 shows the cDNA sequence of a human orthologue of H38K22.2 (780 bp).
- SEQ ID NO. 13 shows the deduced amino acid sequence of a human orthologue of H38K22.2 (260 aa).
- 15

The following examples illustrate the present invention without, however, limiting the same thereto.

20

EXAMPLE 1: Generation of dsRNA molecules for RNAi experiments

First, oligonucleotide primer pair sequences were selected to amplify portions of the gene of interest's coding region using standard PCR techniques. Primer pairs were chosen to yield PCR products containing at least 500 bases of coding sequence, or a maximum of

25

- 25 -

coding bases for genes smaller than 500 bases. In order to permit the subsequent use of the PCR product as a template for *in vitro* RNA transcription reactions from both DNA strands, the T7 polymerase promoter sequence "TAATACGACTCACTATAGG" was added to the 5' end of forward primers, and the T3 polymerase promoter sequence "AATTAACCCTCACTAAAGG" was added to the 5' end of reverse primers. The synthesis of oligonucleotide primers was completed by a commercial supplier (Sigma-Genosys, UK or MWG-Biotech, Germany).

PCR reactions were performed in a volume of 50 µl, with Taq polymerase using 0.8 µM primers and approximately 0.1 µg of wild-type (N2 strain) genomic DNA template. The PCR products were EtOH precipitated, washed with 70% EtOH and resuspended in 7.0 µl TE. 1.0 µl of the PCR reaction was pipetted into each of two fresh tubes for 5 µl transcription reactions using T3 and T7 RNA polymerases. The separate T3 and T7 transcription reactions were performed according to the manufacturer's instructions (Ambion, Megascript kit), each diluted to 50 µl with RNase-free water and then combined.

The mixed RNA was purified using RNeasy kits according to the manufacturer's instructions (Qiagen), and eluted into a total of 130 µl of RNase-free H₂O. 50 µl of this was mixed with 10 µl 6X injection buffer (40 mM KPO₄ pH 7.5, 6 mM potassium citrate, pH 7.5, 4% PEG 6000). The RNA was annealed by heating at 68°C for 10 min, and at 37°C for 30 min. Concentration of the final dsRNAs were measured to be in the range of 0.1-0.3 µg/µl. The products of the PCR reaction, of the T3 and T7 transcription reactions, as well as the dsRNA species were run on 1% agarose gels to be examined for quality control purposes. Success of double stranding was assessed by scoring shift in gel mobility with respect to single stranded RNA, when run on non-denaturing gels.

EXAMPLE 2: Injections of dsRNA and phenotypic assays

dsRNAs were injected bilaterally into the syncitial portion of both gonads of wild-type (N2 strain) young adult hermaphrodites, and the animals incubated at 20°C for 24 hrs. Embryos were then dissected out from the injected animals and analyzed by time-lapse

- 26 -

differential interference contrast videomicroscopy for potential defects in cell division processes, capturing 1 image every 5 seconds, as previously described (Gönczy *et al.*, Dissection of cell division processes in the one cell stage *Caenorhabditis elegans* embryo by mutational analysis. *J Cell Biol* 144, 927-946 (1999)). For each experiment, embryos
5 from at least 3 different injected worms were filmed in this manner, from shortly after fertilization until the four cell stage. Embryos from 2 additional injected worms were also recorded via still images, thus yielding phenotypic documentation for at least 5 injected worms in each experiment.

In some cases, embryos exhibited acute sensitivity to osmotic changes, as evidenced by
10 their loss of structural integrity during the dissection of the injected animals. In order to overcome this limitation, injected animals were not dissected, but rather, anaesthetized for 10 min in M9 medium containing 0.1% tricaine and 0.01% tetramisole, and mounted intact on an agarose pad to observe the F1 embryogenesis *in utero* (Kirby *et al.*, *Dev. Biol.* 142, 203-215 (1990)). The resolution achieved by viewing through the body wall does not equal
15 that achieved by observing dissected embryos, and only limited phenotypic analysis was conducted in these cases.

Three injected animals were also transferred to a fresh plate 24 hrs after injection of dsRNA, and left at 20°C. Two days later, the plate was checked with a stereomicroscope (20-40x total magnification) for the presence of F1 larvae (L2's-L4's), as well as their
20 developmental stage. Two days after that, the plate was inspected again for the presence of F1 adults, as well as their overall body morphology and the presence of F2 progeny.

EXAMPLE 3: Characterization of the *C. elegans* gene H38K22.2

25 Two dsRNAs, "300C3" and "340G12", were designed and used to specifically silence the expression of the *C. elegans* gene H38K22.2 by RNAi, thereby testing its functional involvement in the first 2 rounds of embryonic cell division in this metazoan species. The dsRNAs were synthesized *in vitro* from PCR-amplified wild type genomic DNA fragments
30 of the H38K22.2 gene. For the PCR, two sets of primer pairs were used:

- 27 -

"TCAATCAGTATGTCGACCC" with "GGAAGAAATTGGGGAAACA" as forward and reverse primers, respectively, to generate dsRNA "300C3", and "ATCGAGCGCCTCTTCAATC" with "TGGTGTCTCCATTTGCTGA" as forward and reverse primers, respectively, to generate dsRNA "340G12". The dsRNAs were purified, and injected into adult hermaphrodite worms. The phenotypic consequences of the RNAi treatment were documented 24 hours later in the F1 progeny of injected worms, using time-lapse differential interference contrast (DIC) microscopy. Embryo recordings started ~20 minutes after fertilisation, while the female pronucleus is completing its meiotic divisions, until the 4 cell stage, ~30 minutes later.

In the F1 progeny of control worms that were either not injected, or injected with irrelevant dsRNA, the cellular events of the first two rounds of embryonic cell division were found to exhibit very limited variability, as observed by DIC microscopy. All processes that were examined and scored for the possibility of phenotypic deviations are listed and illustrated in Figure 1. Briefly, the antero-posterior polarity of the embryo is initially determined by the position of the male pronucleus at the cortex, shortly after entry into the egg (right arrow in Fig. 1a). This is accompanied by a clear, coordinated flow of yolk granules through the central portion of the cytoplasm along the embryo's longitudinal axis towards the male pronucleus, and a concomitant series of cortical waves or ruffles progressing towards the anterior of the embryo (left side in Fig.1). Shortly thereafter, the male and female pronuclei undergo highly patterned migrations (right and left arrows respectively, in Fig. 1a,b) resulting in their meeting within the posterior half of the embryo (Fig. 1c), followed by a centration and rotation (Fig. 1d) of the pronuclear pair and associated centrosomes (arrowheads in Fig. 1b-d) to set up the future mitotic spindle along the embryo's longitudinal axis. After synchronous breakdown of the pronuclear envelopes, the clearly bipolar mitotic spindle is initially short (Fig. 1e), but then elongates while exhibiting clear lateral "rocking" movements of the posterior pole (Fig. 1f-h). These movements are accompanied by a slight posterior displacement of the posterior spindle pole, while the anterior spindle pole remains approximately stationary. This then results in an asymmetric positioning of the spindle during anaphase and telophase, thereby yielding an asymmetric placement of the cytokinetic furrow (arrowheads in Fig. 1i,j), and generating unequally-sized daughter cells: a smaller posterior P1 blastomere (right cell in Fig. 1k-o), and larger anterior AB blastomere (left cell in Fig. 1k-n). While the AB nucleus

- 28 -

then migrates directly to the center of the AB cell (left arrow in Fig. 1k-l), the P1 nucleus typically migrates further towards the posterior of that cell (right arrow in Fig. 1k-l), before undergoing a pronounced 90° rotation while re-migrating to the anterior P1 cortex with one of its duplicated centrosomes leading (arrowheads in Fig. 1m). This insures that the P1 blastomere then divides along the embryo's longitudinal axis, perpendicular to that of the AB blastomere (Fig. 1n, arrowheads indicate centrosomes). These two divisions occur asynchronously, with P1 lagging 2-3 minutes behind AB (Fig. 1 n-p).

In the F1 embryos of worms injected with dsRNAs "300C3" or "340G12", the following highly reproducible phenotypes are observed (Fig. 2). First, although the dynamics of female pronuclear migration appear normal in all cases, its initiation is often somewhat delayed. Meeting and apposition of the two pronuclei also typically exhibits defects in that the female pronucleus gets captured by only one of the two centrosomes associated with the male pronucleus (compare Fig. 2a-c with Fig. 1a-c). Although this defect is usually corrected before pronuclear envelope breakdown is completed, subsequent positioning of the mitotic spindle within the embryo often appears defective. Weak manifestation of this phenotype appears as a lack of rocking of the posterior spindle pole during anaphase, while more severe cases show a notable drift of the entire spindle towards the posterior or lateral cortex, reaching the cortex itself and losing its longitudinal alignment completely. In the latter cases, the strongly aberrant spindle position gives rise to inappropriate specification of cleavage furrow formation, leading to anomalous cytokinesis. Even in cases where spindle position appears relatively normal, positioning of the daughter Nucleus-Centrosomes-Complexes (NCCs) typically appears abnormal as soon as anaphase ends and the cleavage furrow ingresses. This is often particularly visible in the AB blastomere, where the NCC, instead of moving directly to the centre of the cell starting at telophase, first migrates anteriorly in close proximity to the lateral cortex before eventually centering (Fig. 2a-k). This defect is usually accompanied by an apparent absence of interzonal spindle microtubules at telophase and a notable bifurcation or forking of the cytokinetic cleavage furrow (arrows in Fig. 2 g), leading to aberrantly-sized daughter blastomeres or even failure of cytokinesis by complete regression of the furrow (Fig. 2g-m). Nuclear migration and positioning of the P1 nucleus is also aberrant in most cases, resulting in a significant delay - or in some cases, a complete failure - in achieving its expected 90° rotation and association with the anterior cortex. Division of the P1 blastomere is often

- 29 -

significantly delayed in such embryos. Finally, defects in female meiotic divisions are also occasionally observed, as evidenced by the presence of multiple female pronuclei, indicating a failure to successfully extrude one or both polar bodies, which could come from cytokinetic defects similar to those noted above.

5 All observed phenotypes indicate a requirement for H38K22.2 gene function in the microtubule-dependent cellular positioning of NCCs and spindles during mitosis, and possibly meiosis. Since this function is essential to cell cycle progression and cell division throughout metazoans, this gene and any homologues and derivatives thereof represent excellent tools for use in the development of a wide range of therapeutics including anti-
10 proliferative agents. Analysis of the H38K22.2 gene sequence reveals clear orthologues in human (NCBI Accession # AAH09478), mouse (NCBI Accession # AAF04863) and *Drosophila* (NCBI Accession # CG7427) (see Fig. 5), all of which have had no known functions ascribed to them until now. Based on their extremely high level of sequence conservation at the protein level, it can be concluded that all of these genes most likely
15 encode proteins with equivalent functions in each of their respective species. The 336 residue protein encoded by the H38K22.2 gene isoform "a" exhibits no known structural motifs or consensus domains, according to either SMART or CDD analyses.

20 **EXAMPLE 4: Characterization of the *C. elegans* gene C02F5.1**

A dsRNA, "307C1", was designed and used to specifically silence the expression of the *C. elegans* gene C02F5.1 by RNAi, thereby testing its functional involvement in the first 2 rounds of embryonic cell division in this metazoan species. The dsRNA was synthesized *in*
25 *vitro* from a PCR-amplified wild type genomic DNA fragment of the C02F5.1 gene. For the PCR, oligonucleotides with sequences "ATCTGAAGATCCGTCCACT" and "ATGCACAATGGGTATTTTT" were used as forward and reverse primers, respectively, to generate dsRNA "307C1" which was purified, and injected into adult hermaphrodite worms. The phenotypic consequences of the RNAi treatment were documented 24 hours
30 later in the F1 progeny of injected worms, using time-lapse differential interference contrast (DIC) microscopy. Embryo recordings started ~20 minutes after fertilisation,

- 30 -

while the female pronucleus is completing its meiotic divisions, until the 4 cell stage, ~30 minutes later.

In the F1 progeny of control worms that were either not injected, or injected with irrelevant dsRNA, the cellular events of the first two rounds of embryonic cell division were found to exhibit very limited variability, as observed by DIC microscopy. All processes that were examined and scored for the possibility of phenotypic deviations are listed and illustrated in Figure 1.

F1 embryos from parent worms injected with dsRNA "307C1" are consistently found to exhibit the following phenotypes (Fig. 3). First, all cellular processes that are scorable by DIC microscopy until entry into mitosis are typically indistinguishable from the wild type pattern. These include egg shape and size, yolk granule size and density, yolk granule flows and cortical ruffling, pseudo-cleavage furrow formation and positioning, pronuclear appearance (arrows in Fig. 3a) and migration (Fig. 3a,b), as well as centration and rotation of pronuclei (Fig. 3b,c) and associated pair of centrosomes (arrowheads in Fig. 3b,c). Formation and positioning of the bipolar mitotic spindle also take place normally, but the spindle is most often thinner and less rigid than in wild type, exhibiting aberrant lateral bending during its rocking and elongation at anaphase (Fig. 3f-i). After completion of cytokinesis, which appears normal, the reforming daughter nuclei are typically tear-shaped, and remain close to the newly-formed cortex for a prolonged period (Fig. 3a and k). Consistent with the tear shape, the two nuclei remain often physically connected by anomalous chromatin bridges and karyomeres are also typically seen (asterisks in Fig. 3k and l). This phenotype subsequently results in embryonic lethality in all cases.

The absence of defects in pronuclear migration and assembly of the bipolar spindle argue against a role for this gene in more general microtubule functions. The observed defects are consistent with a failure in mitotic chromosome segregation, most likely in the separation of sister chromatids, resulting in the formation of chromatin bridges, which then persist at telophase. The present data therefore indicate an essential requirement for C02F5.1 gene function in mitotic chromosome segregation. Since this function is essential to cell cycle progression and cell division throughout metazoans, this gene and any

homologues and derivatives thereof represent excellent tools for use in the development of a wide range of therapeutics including anti-proliferative agents.

Analysis of the C02F5.1 sequence reveals that the encoded 1010 residue protein contains regions predicted to form coiled coil structures, i.e. likely protein-protein interaction domains. Sequence homology analyses using the BLASTp program presently reveal no clearly orthologous sequences in other organisms. However, considering the essential and highly conserved nature of the cellular process in question, functional orthologues of this gene/protein are extremely likely to exist in all metazoans, possibly in all eukaryotes, and will be identified using for example the methodology as outlined in EXAMPLE 6.

10

EXAMPLE 5: Characterization of the *C. elegans* gene F10E9.8

15

Two dsRNAs, "305A12" and "341G5", were designed and used to specifically silence the expression of the *C. elegans* gene F10E9.8 by RNAi, thereby testing its functional involvement in the first 2 rounds of embryonic cell division in this metazoan species. The dsRNAs were synthesized *in vitro* from PCR-amplified wild type genomic DNA fragments of the F10E9.8 gene. For PCR, two sets of primer pairs were used: "TTCGTCTCGAACACGTATATCCT" with "GAAAGAAGATGAATCAGGCATTG" as forward and reverse primers, respectively, to generate dsRNA "305A12", and "CTGCAAAAATTATGACTGTGTCTG" with "AGCATTGAGATTTGGTTGTCC" as forward and reverse primers, respectively, to generate dsRNA "341G5". The dsRNA was purified, and injected into adult hermaphrodite worms. The phenotypic consequences of the RNAi treatment were documented 24 hours later in the F1 progeny of injected worms, using time-lapse differential interference contrast (DIC) microscopy. Embryo recordings started ~20 minutes after fertilisation, while the female pronucleus is completing its meiotic divisions, until the 4 cell stage, ~30 minutes later.

In the F1 progeny of control worms that were either not injected, or injected with irrelevant dsRNA, the cellular events of the first two rounds of embryonic cell division were found to

30

- 32 -

exhibit very limited variability, as observed by DIC microscopy. All processes that were examined and scored for the possibility of phenotypic deviations are listed and illustrated in Figure 1.

In the F1 embryos of worms injected with dsRNAs "305A12" or "341G5", the following highly reproducible phenotypes are observed (Fig. 4). First, all cellular processes that are scorable by DIC microscopy until the 2-cell stage are typically indistinguishable from the wild type pattern. These include egg shape and size, yolk granule size and density, yolk granule flows and cortical ruffling, pseudo-cleavage furrow formation and positioning, pronuclear appearance (arrows in Fig. 4a) and migration (Fig. 4a,b), as well as centration and rotation of pronuclei (Fig. 4b,c) and associated pair of centrosomes (arrowheads in Fig. 4b,c). The first round of division also occurs without any detectable deviations from wild type (Fig. 4d-h). It should particularly be noted that no defects are observed with respect to size, number or positioning of centrosomes or spindle poles in the single cell embryo (note arrowheads in Fig. 4b-f). In the two-cell stage embryo, however, although nuclear positioning also remains equivalent to wild type, an apparent failure in centrosome duplication is consistently observed in one of the two blastomeres and sometimes in both. A single perinuclear centrosomal region, as seen by its exclusion of yolk granules (black arrowhead in Fig. 4h-j), is typically observed instead of the two normally seen both in wild type embryos and in the unaffected blastomere (white arrowheads in Fig. 4i,j). Despite the apparent failure in centrosome duplication, microtubule-dependent processes continue normally, as illustrated by the successful anterior migration of the P1 nucleus, with its single centrosomal region leading (black arrowhead in Fig. 4h-j). Upon entering mitosis, as scored by nuclear envelope breakdown, the defective blastomere then fails to generate a bipolar spindle, forming instead a monopolar array of microtubules (dashed circle in Fig. 4k), as evidenced by the radial alignments of yolk granules in that region. Cytokinesis fails to occur in that blastomere, resulting in reformation of multiple, irregularly sized nuclei, known as karyomeres (arrows in Fig. 4m,n). In contrast, all aspects of cell division occur normally in the neighboring blastomere, resulting in normal daughter cells, each containing a single equal-sized nucleus (arrows in Fig. 4l).

The complete failure in bipolar spindle formation, accompanied by the presence of a single centrosomal region instead of two in the affected two-cell stage blastomere, clearly

- 33 -

indicates a requirement for F10E9.8 gene function in the complex process of mitotic spindle assembly. However, the lack of detectable defects in other microtubule-dependent processes including pronuclear migration and spindle function in the single-cell embryo effectively rules out a general microtubule-related function. In view of the maternal nature
5 of the RNAi effect and the fact that the egg inherits its first centrosome paternally, the successful generation of a bipolar spindle in the single-cell embryo further suggests that F10E9.8 function may, in fact, be required for some aspect of centrosome duplication or separation.

Indeed, since sperm development is fully completed within the parent before initiation of
10 the RNAi treatment, it remains unaffected by the injected dsRNA. This results in the donation of an intact "wild type" centrosome from the sperm to the egg at fertilisation. After fertilisation, this already bipartite centrosome (i.e. containing two "replication units", as evidenced by the presence of two centrioles) undergoes one round of duplication, as observed in other systems by the budding of a new centriole barrel from each existing
15 centriole. This is followed by a physical separation of the two centriole pairs and associated pericentriolar material. This process is not dependent on the prior duplication event, and is solely needed to insure the successful formation of the bipolar spindle to be used in the first round of embryonic cell division. It therefore appears that F10E9.8 function is most likely not required for this process.

20 5. If the first duplication round fails, however, bipolar spindle formation is expected to fail during the second round of division, as seen here. Interestingly, the fact that this failure often occurs only in one of the two blastomeres suggests that in these cases only one of the original centrosome's two "replication units" actually failed in its first round of duplication at the single-cell stage. This observation is consistent with findings from other eukaryotes
25 indicating that one of the two replication units contained within the sperm's centrosome actually comes into the egg already fully equipped for one duplication round, while the other must rely on cytoplasmic factors within the egg to permit its own duplication (Sluder, G., Hinchcliffe EH. Control of centrosome reproduction: the right number at the right time. *Biol. Cell.* 91, 413-27 (1999)).

- 34 -

The present findings therefore suggest that the requirement for F10E9.8 function in mitotic spindle assembly most likely results from this gene's essential role in the process of centrosome duplication.

5 Since the process of spindle assembly is essential to cell cycle progression and cell division throughout metazoans, this gene and any homologues and derivatives thereof represent excellent tools for use in the development of a wide range of therapeutics including anti-proliferative agents. Analysis of the F10E9.8 sequence reveals that the encoded 1207
10 residue protein contains one large region predicted to form coiled coil structures, i.e. likely protein-protein interaction domains, and four predicted transmembrane domains. Sequence homology analyses using the BLASTp program presently reveal no clearly orthologous sequences in other organisms. However, considering the essential and highly conserved nature of the cellular process in question, functional orthologues of this gene/protein are extremely likely to exist in all metazoans, possibly all eukaryotes, and will be identified
15 using for example the following methodology.

EXAMPLE 6: Protocol for identifying functional orthologues in other species

20 The present invention describes genes identified as having essential functions in cell division in the model organism *C. elegans*. The basis for performing research in model organisms is that the newly discovered functions for the genes in *C. elegans* will be conserved in other species including humans. Cell division is highly conserved during evolution and therefore the approach of discovering a gene function in *C. elegans* and
25 using the information to characterise or assign functions for the human orthologue is well justified. There are two themes of conservation of genes during evolution. A gene sequence may be conserved. This means that the DNA nucleotide sequence of the gene is very similar in different species, which in turn suggests that the function of the gene is the same in the different species. As is known to any person skilled in the art, a sequence
30 identity or homology above a particular level defines that two genes in different species code for the same gene product and gene function. Homologous genes are typically

- 35 -

identified by performing blast analysis with appropriate software, or by other approaches. For a blast search, an e-value of 10^{-30} will extract the significant homologous sequences. Further phylogenetic analysis can be performed to identify which of the extracted sequences are the orthologues.

- 5 Therefore the following example for identification of orthologues can be presented. A blast search is performed using the blast sequence analysis programs and an e-value of 10^{-3} . An alternative parameter can be the percentage of sequence identity. Over 100 residues, a sequence identity of 30% defines a homologous gene. After the blast search is completed, multiple sequence alignment is performed using appropriate software (for example, 10 CLUSTALW) and a neighbour joining phylogenetic tree is generated. Any person skilled in the art can identify the human orthologue from a phylogenetic tree. Essentially, the human sequence that is separated on the tree by a single speciation event or most closely related on the tree is likely to be an orthologue.

- 15 The second theme of conservation is that the gene function can be conserved with greater divergence of sequence. In the present invention this theme of conservation is not defined. However, if other genes are discovered to have functions that result in the gene product being identified as the same gene product as those claimed in the present invention then the present claims also apply to such genes.

Claims

1. An isolated nucleic acid molecule encoding a polypeptide functionally involved in cell
5 division and proliferation or a fragment thereof and comprising a nucleic acid
sequence selected from the group consisting of:
 - (a) the nucleic acid sequences presented in SEQ ID NO. 1 to 3, SEQ ID NO. 4 to 5,
SEQ ID NO. 6 to 7, SEQ ID NO. 12 and fragments thereof and their
complementary strands,
 - 10 (b) nucleic acid sequences encoding polypeptides that exhibit a sequence identity with
SEQ ID NO. 8, SEQ ID NO. 9, SEQ ID NO. 10, SEQ ID NO. 11 or SEQ ID NO.
13 of at least 25 % over 100 residues and/or which are detectable in a computer
aided search using the blast sequence analysis programs with an e-value of at most
 10^{-30} ,
 - 15 (c) nucleic acid sequences which are capable of hybridizing with the nucleic acid
sequences of (a) or (b) under conditions of medium/high stringency,
 - (d) nucleic acid sequences which are degenerate as a result of the genetic code to any
of the sequences defined in (a), (b) or (c).
2. A nucleic acid probe comprising a nucleic acid sequence as defined in claim 1 which
20 may be a polynucleotide or an oligonucleotide comprising at least 15 nucleotides
containing a detectable label.
3. A recombinant vector or nucleic acid construct having incorporated therein the
isolated nucleic acid molecule of claim 1 or a fragment thereof.
- 25 4. The vector of claim 3 which is an expression vector.
5. A host cell which has been genetically engineered to incorporate therein the isolated
nucleic acid molecule of claim 1 or the recombinant vector or nucleic acid construct of
claim 3.
- 30 6. The host cell of claim 5 having incorporated therein the expression vector of claim 4.

7. An assay kit comprising the isolated nucleic acid molecule or a fragment thereof of claim 1 or the probe of claim 2 in a suitable container.

5 8. A method for producing a polypeptide functionally involved in cell division and proliferation or a fragment thereof in a host cell comprising the steps

(a) transferring the expression vector of claim 4 into a suitable host cell, and

(b) cultivating the host cells of step (a) under conditions which will permit the expression of said polypeptide or fragment thereof and

10 (c) optionally, secretion of the expressed polypeptide into the culture medium.

9. Use of a probe as defined in claim 2 to isolate orthologues of genes comprising the nucleic acid sequences as disclosed in SEQ ID NO. 1 to 3, SEQ ID NO. 4 to 5, SEQ ID NO. 6 to 7, SEQ ID NO. 11.

15

10. Use of the isolated nucleic acid molecule or a fragment thereof as defined in claim 1 for producing a polypeptide functionally involved in cell division and proliferation or a fragment thereof.

20 11. Use of a nucleic acid molecule or a fragment thereof as defined in claim 1 or of the probe of claim 2 in a screening assay for interacting drugs that inhibit, stimulate or effect the cell division or proliferation.

25 12. Use of a nucleic acid molecule as defined in claim 1 or of the probe of claim 2 in a method for diagnosis or treatment of diseases associated with anormalous and/or excessive cell division or proliferation.

30 13. The use of claim 12 wherein the disease is a coronary restenosis or a neoplastic disease selected from the group consisting of lymphoma, lung cancer, colon cancer, ovarian cancer and breast cancer.

14. A polypeptide functionally involved in cell division and proliferation or a fragment thereof comprising an amino acid sequence selected from the group consisting of:

(a) the amino acid sequences depicted in SEQ ID NO. 8, 9, 10, 11 and 13 and fragments thereof,

(b) amino acid sequences which exhibit a sequence identity with the sequences of (a) of at least 25 % over 100 residues and/or which are detectable in a computer aided search using the BLAST sequence analysis programs with an e-value of at most 10^{-30} ,

(c) amino acid sequences encoded by any of the nucleic acid sequences (c) – (d) as defined in claim 1.

15. A fusion protein comprising the polypeptide or fragment thereof of claim 14.

16. An antibody or a fragment thereof capable of specifically binding with the polypeptide of claim 14 or with an immunogenic part thereof.

17. A humanized antibody capable of specifically binding with the polypeptide of claim 14 or with an immunogenic part thereof.

18. An assay kit comprising the polypeptide as claimed in claim 14, the fusion protein as claimed in claim 15, or the antibodies as claimed in claims 16 and/or 17 in a suitable container.

19. Use of the polypeptide of claim 14, of the fusion protein of claim 15, or of the antibodies of claims 16 or 17 in a screening assay for interacting drugs that inhibit, stimulate or effect the cell division or proliferation.

20. The use of a polypeptide or of an antibody as claimed in claim 19 wherein the screening assay for interacting drugs comprises the following steps:

1. recombinant expression of said polypeptide in a host cell
2. isolation and optionally purification of the recombinantly expressed polypeptide of step 1
3. optionally labelling of the drugs that are tested to interact with said polypeptide and/or labelling of the recombinantly expressed polypeptide
4. immobilization of the recombinantly expressed polypeptide to a solid phase
5. binding of a potential interaction partner or a variety thereof to the polypeptide
6. optionally one or more washing steps
7. detection and/or quantification of the interaction, in particular by monitoring the amount of label remaining associated with the solid phase over background levels.

21. Use of the polypeptide of claim 14, of an amino acid sequence as defined in claim 14 or of the antibodies of claims 16 or 17 in a method for diagnosis or treatment of diseases associated with anomalous and/or excessive cell division or proliferation.

22. The use of claim 20 wherein the disease is a coronary restenosis or a neoplastic disease selected from the group consisting of lymphoma, lung cancer, colon cancer, ovarian cancer and breast cancer.

22. Use of the nucleic acid sequences as defined in claim 1 or the amino acid sequences as defined in claim 14 for developing computational models, structural models or other models for evaluating drug binding and efficacy.
